

The impact of dissociation on transposon-mediated disease control strategies

John Marshall, Department of Biomathematics, UCLA

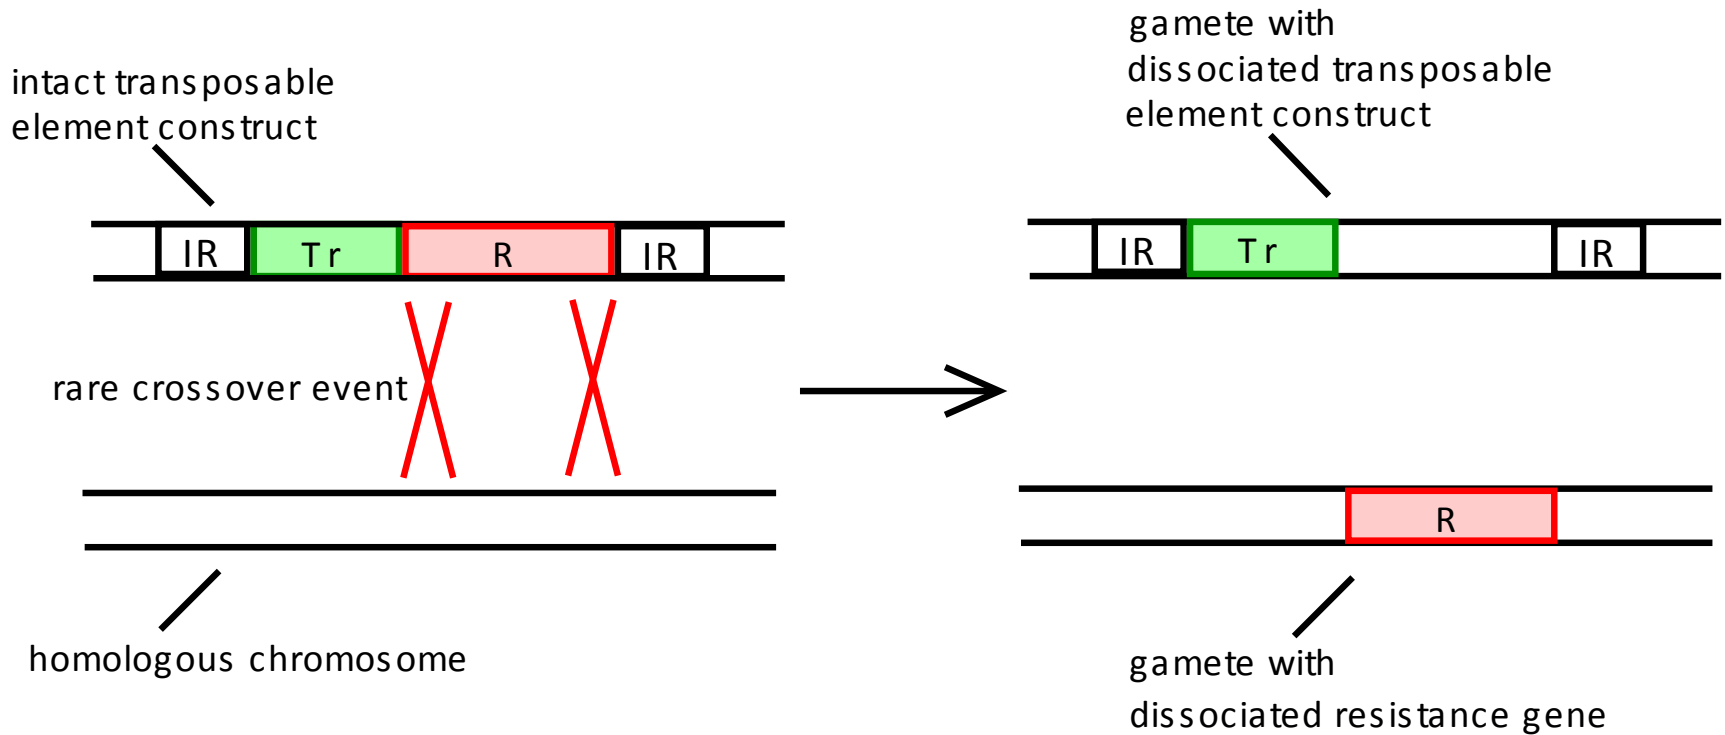

“It is misguided to continue to use scarce resources from the malaria-research budget for activities which could not control malaria but only produce NPS (Nature-paper synthetase).”

C. F. Curtis, Ecological aspects for application of genetically modified mosquitoes (2003).

How is linkage lost between a TE and resistance gene?

1. Rare recombination events

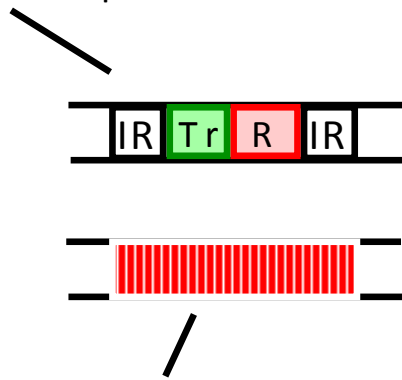

2. Internal deletion of DNA sequences within a TE

2. Abortive gap repair (Part 1)

2. Abortive gap repair (Part 2)

homologous chromosome,
sister chromatid,
or ectopic chromosomal site

gap in host chromosome

gap repair
mechanism

successful
gap repair

abortive
gap repair

dissociated
transposable element
construct

Measurement of dissociation rate for *P* elements in *D. melanogaster*

Phenotype:	Interpretation:
Wild-type female	Non-excision
White-eyed male	Non-insertion
White-eyed female	Excision
Wild-type male	Insertion

Dissociation rate
= $0.05 \text{ TE}^{-1}\text{gen}^{-1}$

W. R. Engels, *Mobile DNA*
(1989).

Internal deletion rates vary between TEs and host species:

Fast:	Slow:
<ul style="list-style-type: none">• <i>P</i> and <i>hobo</i> elements in <i>Drosophila melanogaster</i>• <i>Ds</i> elements in maize	<ul style="list-style-type: none">• <i>Herves</i> element in <i>Anopholes gambiae</i> remains almost exclusively intact throughout evolutionary history

Question: What rate of dissociation can be tolerated by a TE-mediated disease control strategy?

Question: What if the resistance gene compromises the transposition rate?

Exogenous DNA used to increase transposon size

D. J. Lampe *et al.*, *Genetics* (1988).

Question: What if the resistance gene has an impact on the host fitness?

Fitness cost:	Fitness benefit:
<ul style="list-style-type: none">•Mounting an immune response is generally associated with an evolutionary cost in insects	<ul style="list-style-type: none">•Transgenic mosquitoes have been created that have no noticeable fitness cost when fed on <i>Plasmodium</i>-free blood•These mosquitoes are in fact more fit when fed on <i>Plasmodium</i>-infected blood

M. T. Marrelli *et al.*, *PNAS* (2007),
L. A. Moreira *et al.*, *Genetics* (2004),
A. R. Kraaijeveld & H. C. Godfray, *Nature* (1997).

Mathematical model:

$$x_{(m,n)}(t)$$

= proportion of disease vectors having:
 m copies of the intact construct and
 n copies of the dissociated construct
at time t

Total birth rate = Total death rate

Birth rate:

- All TE copies segregate independently

Death rate:

- Function of copy number
- Impact of resistance gene

Changes in host genotype:

Transposition:

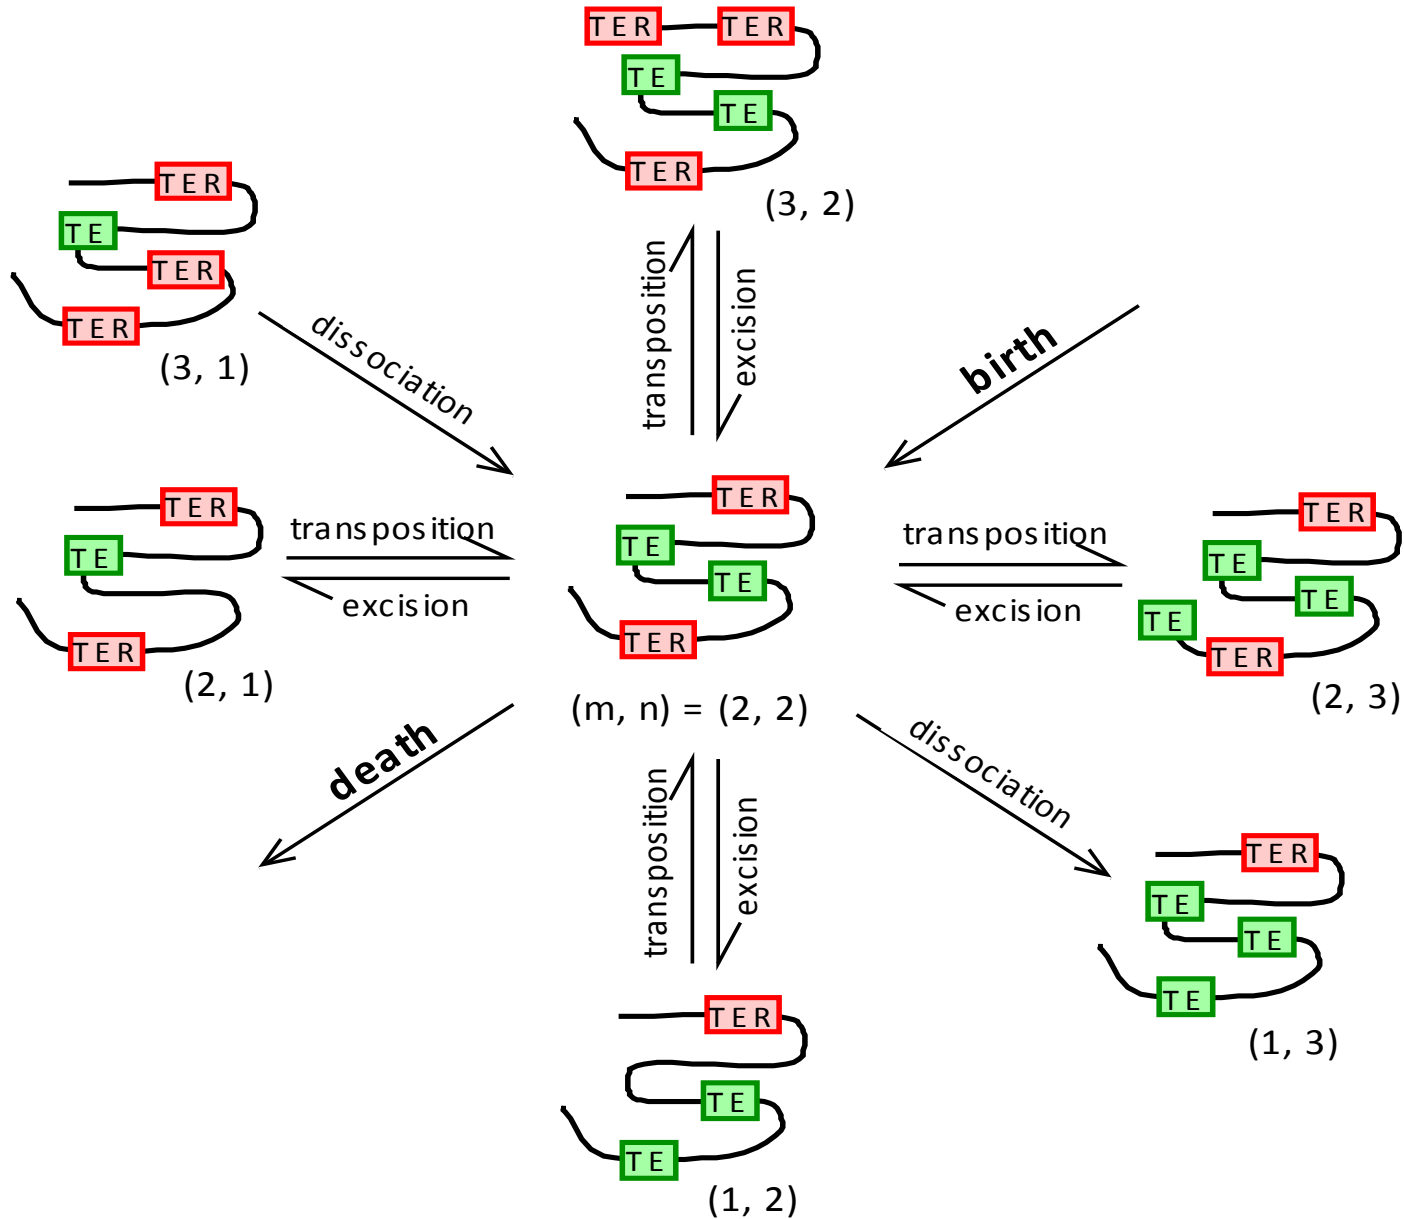

- Repression with increasing copy number
- Handicap of resistance gene

Deletion

Dissociation:

- Proportional to transposition rate

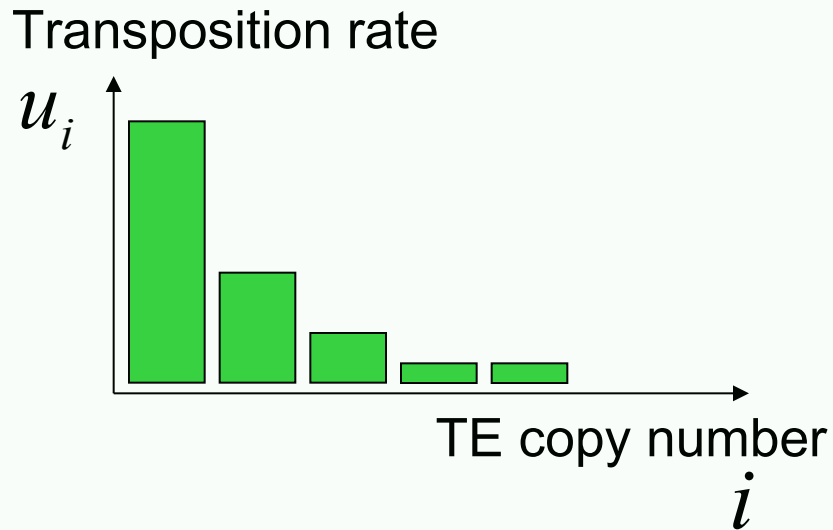

Mathematical model:

Mathematical model:

Repression of transposition

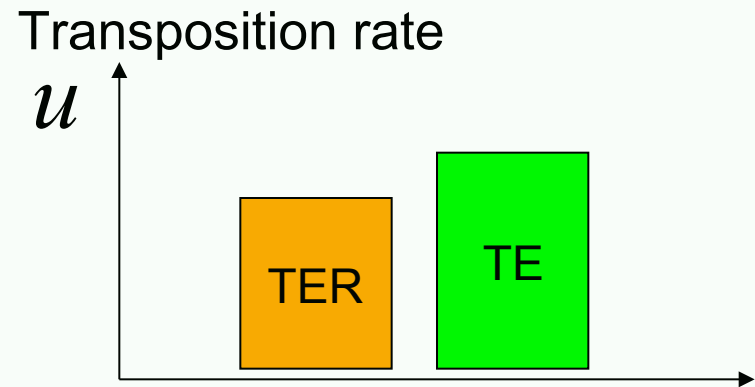

$$u_i = u_1 2^{-c(i-1)}$$

Sources:

- Self repression
- Host repression

Handicap of resistance gene

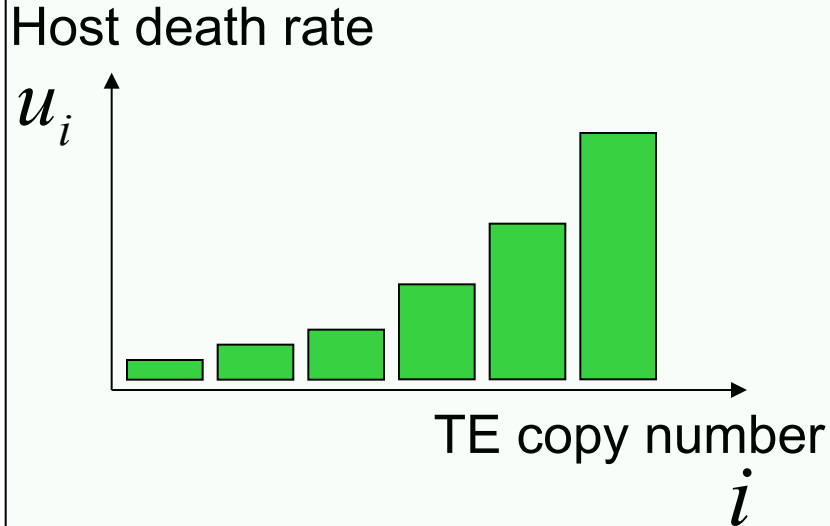

$$u_{TER} = (1 - \delta)u_{TE}$$

Default parameter values:

- $u_1 = 0.1 \text{ TE}^{-1}\text{gen}^{-1}$
- $c = 3$

Host fitness

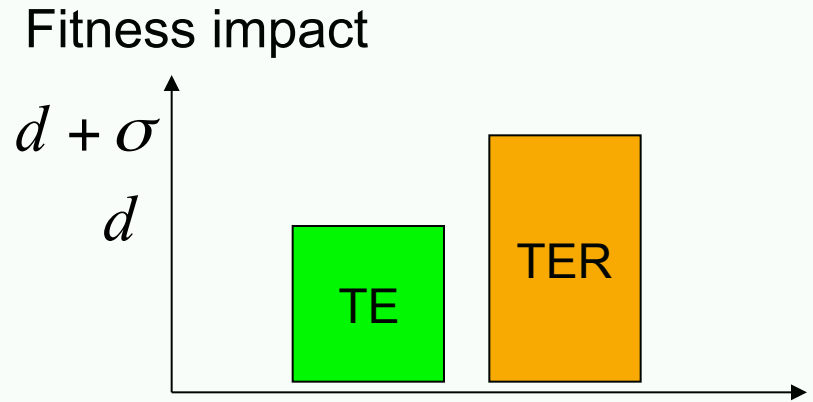

$$\mu_i = 1 + di^p$$

Sources:

- Insertional mutagenesis
- Ectopic recombination
- Act of transposition

Fitness impact of resistance gene

$$\mu_{(m,n)} = 1 + \left(d + \frac{m}{m+n} \sigma \right) (m+n)^p$$

Default parameter values:

- $\mu_1 = 0.001 \text{ TE}^{-1}\text{gen}^{-1}$
- $p = 1.5$

What this all means mathematically

Birth

Death

$$\frac{dx_{(m,n)}(t)}{dt} = \theta(t) \sum_{i,j,k,l} P_{(i,j),(k,l),(m,n)} x_{(i,j)}(t) x_{(k,l)}(t) - \mu_{(m,n)} x_{(m,n)}(t)$$

$$+ (m-1)(1-\delta)u_{m+n-1} x_{(m-1,n)}(t) + (n-1)u_{m+n-1} x_{(m,n-1)}(t)$$

$$+ (m+1)v x_{(m+1,n)}(t) + (n+1)v x_{(m,n+1)}(t)$$

$$+ (m+1)w_{(m+1,n-1)} x_{(m+1,n-1)}(t)$$

$$- \left\{ m(1-\delta)u_{m+n} + nu_{m+n} + mv + nv + mw_{(m,n)} \right\} x_{(m,n)}(t)$$

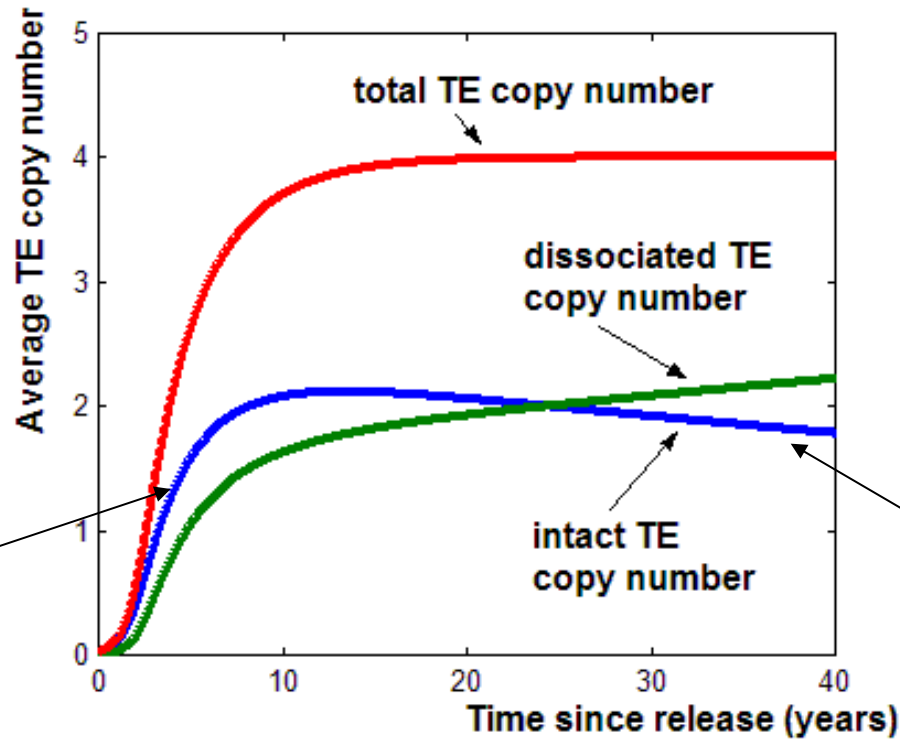

Dissociation

Transposition

Deletion

Loss of resistance gene is most rapid during the early stages of TE spread

Dissociation rate = $0.01 \text{ TE}^{-1}\text{gen}^{-1}$:

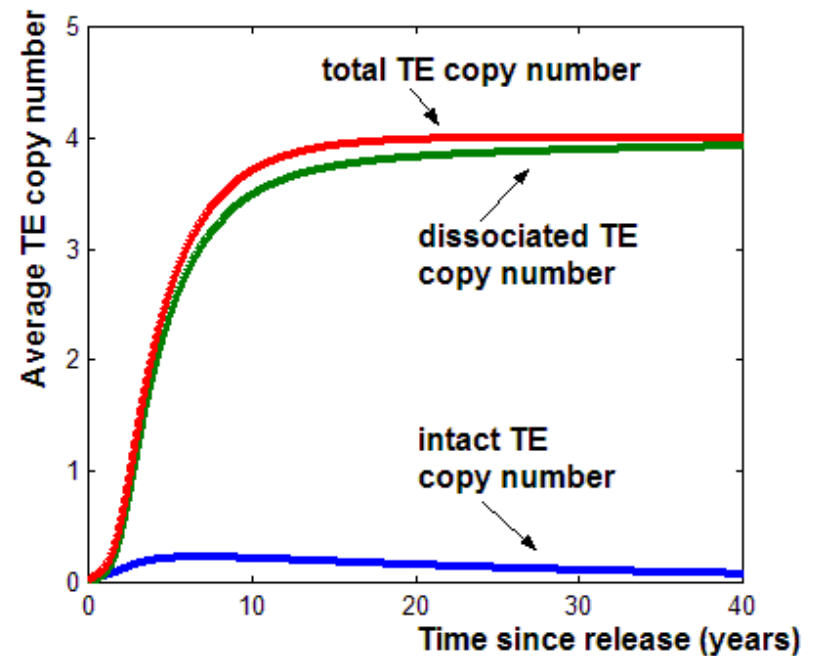

Dissociation often occurs during the act of transposition; hence the proportion of dissociated TEs increases rapidly early on.

Following equilibrium, transposition still occurs to counteract selection and excision; hence the proportion of dissociated TEs continues to decrease slowly.

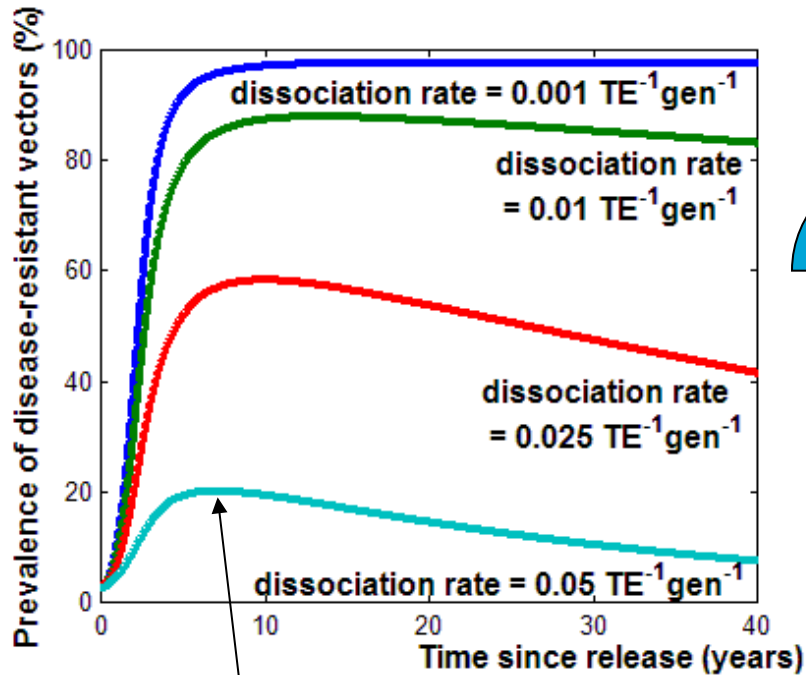

Loss of resistance gene depends strongly on dissociation rate

Dissociation rate = $0.001 \text{ TE}^{-1}\text{gen}^{-1}$:

Dissociation rate = $0.05 \text{ TE}^{-1}\text{gen}^{-1}$:

Prevalence of disease-resistant vectors strongly depends on dissociation rate

For P elements in *D. melanogaster*, the resistance gene would reach a maximum prevalence of ~20%

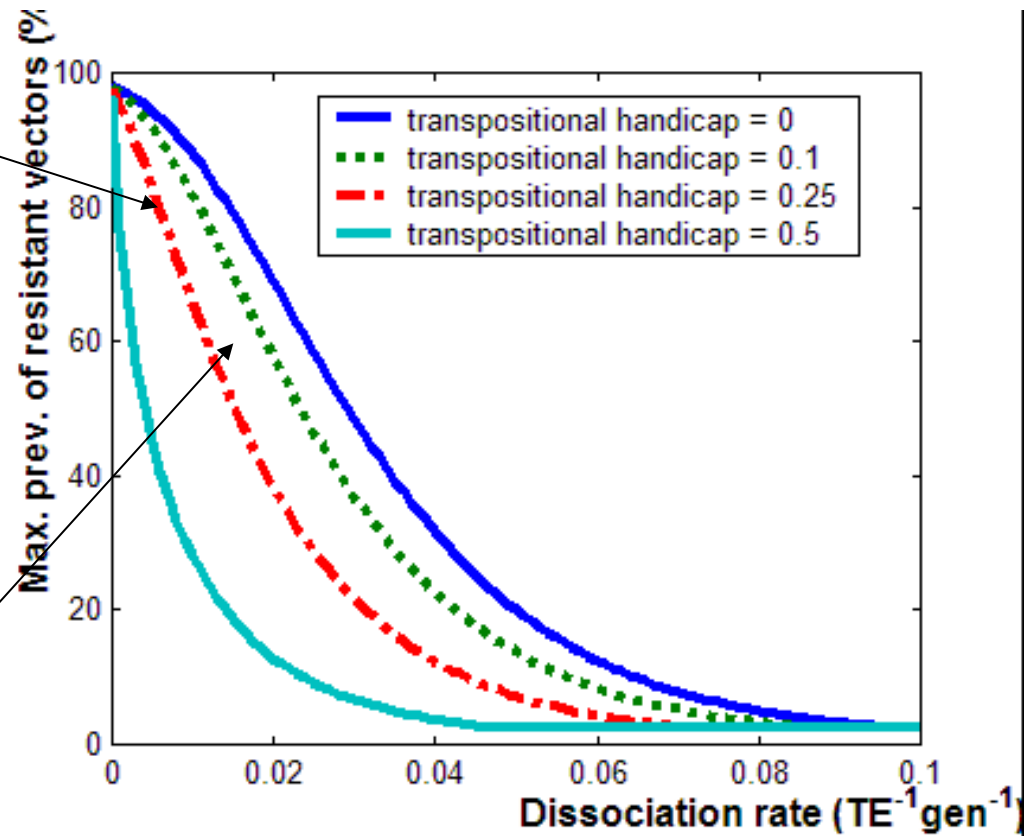

For dissociation rates $< 0.013 \text{ TE}^{-1}\text{gen}^{-1}$, the disease resistance gene reaches a maximum prevalence of $< 80\%$

Transpositional handicap reduces the prevalence of disease-resistance

For transpositional handicaps > 0.25 , dissociation rate must be extremely small to achieve a high maximum prevalence

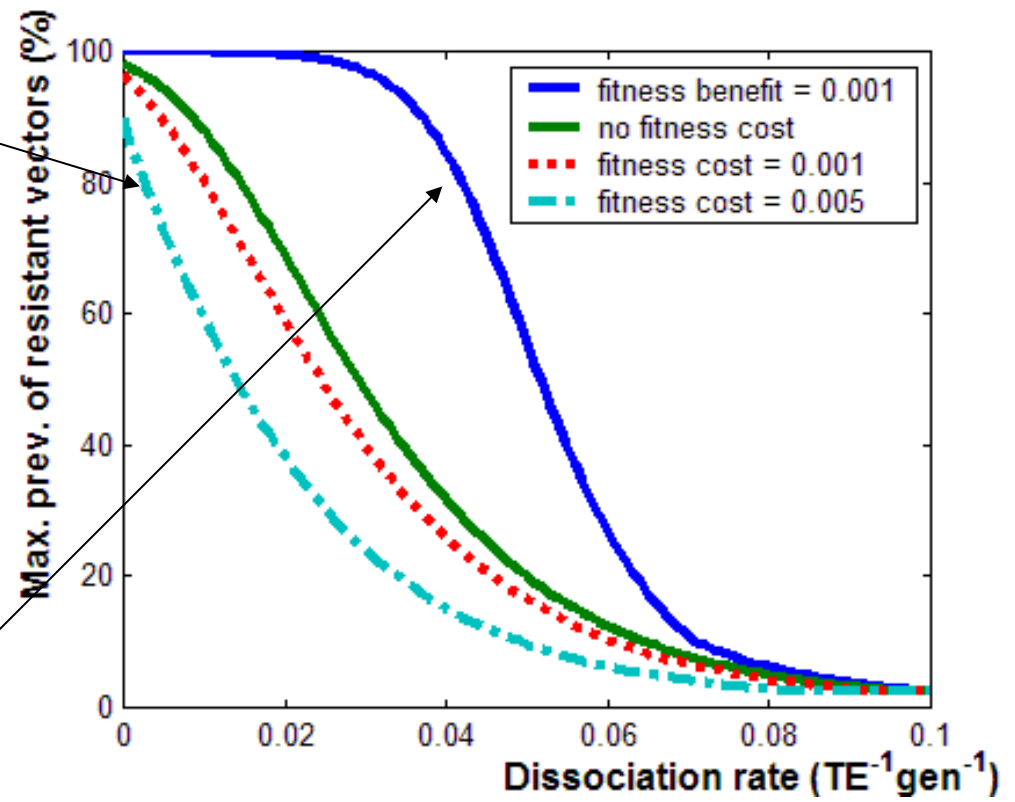

For a *Himar1* element increased in size by $\sim 75\%$, the transpositional handicap is ~ 0.18

Fitness benefit greatly increases the prevalence of disease-resistance

For a fitness cost $> 0.005 \text{ TE}^{-1}$, dissociation rate must be extremely small to achieve a high maximum prevalence

For a fitness benefit as small as 0.001 TE^{-1} , the dissociation rate required for disease control is greatly relaxed

Model conclusions

Dissociation rate:

- Critical parameter in determining the fate of the gene drive strategy
- **Recommend dissociation rate $< 0.01 \text{ TE}^{-1}\text{gen}^{-1}$**
- If the dissociation rate is too large, then the introduction of resistance genes is reversible within a human time frame

Selective advantage of resistance gene:

- Not sufficient to drive resistance gene into population on its own
- When combined with gene drive strategy, greatly improves chances of success
- **A fitness benefit $\sim 0.001 \text{ TE}^{-1}$ will make disease control realistic for moderate dissociation rates**

Future research directions

- **Molecular biology:** Measure dissociation rates once transposition has been observed in host species, TEs of interest
- **Ecology:** Continue to seek accurate measurements of fitness consequences of disease-resistance genes
- **Epidemiology:** Imbed the spread of a resistance gene within a model of the epidemiology of malaria or Dengue fever
